Abstract: This study describes a method for swinging up and stabilizing a double inverted pendulum (DIP) in real-time utilizing a PID-LQR combined control system. Firstly, a dynamic model of the double inverted pendulum system is made up and the equations of motion are constructed. The pendulum then is moved from its unstable position to a stable one using a PID-LQR controller. A comparison of the PID-LQR controller’s output and suggestions for improving system stability is presented and is suggested combined control system.

KEYWORDS: Real-time control, Double Inverted Pendulum, PID-LQR Control, Swing Up and Stabilization.

1 Introduction

The control system for swinging up and stabilizing a double inverted pendulum in real-time is introduced in this study. Due to its complex dynamics, the double inverted pendulum is a type of nonlinear system with numerous degrees of freedom. To move the pendulum from an unstable position to a stable one and increase the system's stability, a PID-LQR controller combination is suggested [1], [11]. The equations of motion of the double inverted pendulum system are derived and a dynamic model of the system is established [2]. The PID-LQR controller is designed to generate the control signal to swing up the pendulum [3]. Then, a neural network is used to learn the output of the PID-LQR controller and further improve the stability of the system. Simulation results demonstrate the effectiveness of the combined control system in swinging up and stabilizing the double inverted pendulum in real-time [4].

The double inverted pendulum is an example of a complex, nonlinear dynamic system. It consists of two inverted pendulums attached to each other at their respective centres of mass. This system is unstable and difficult to control, due to the presence of two degrees of freedom and the inherent nonlinearity. In this project, we aim to design a real-time control system that is capable of swinging up and stabilizing the double inverted pendulum using a combination of PID and LQR [5]. The PID-LQR controller is a classical approach to control, which is used to generate control signals that will swing up the pendulum and bring it to a stable equilibrium point. The system is then tested in real-time by simulating the double inverted pendulum in a simulation environment [6]. The results of the real-time simulation show that both the PID-LQR and neural network controllers were successful in swinging up and stabilizing the double inverted pendulum [7]. Overall, this project demonstrates the effectiveness of combining classical and modern control techniques to design a real-time control system for a complex, nonlinear dynamic system [12].

2 Mathematical equations of the double inverted pendulum

The double pendulum model shown in Figure 1 has the DBPEN-LIN attached to the IP02 Linear Servo Base Unit [7]. The positive direction of rotation, when facing the linear cart pinions, is counter-clockwise (CCW) [7]. The zero angle of the pendulums, \( \theta = 0 \) and \( \alpha = 0 \), is defined to be when the two pendulums are perfectly balanced vertically and the positive direction of linear displacement of the IP02 cart is to the right when facing the cart [7].

Figure 1 shows the schematic of DIP system on a cart which will be studied in this project.

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_i} \right) - \frac{\partial T}{\partial q_i} = Q_i, \text{where: } i = [1, 2, 3 \ldots r] \tag{1}
\]

where the \( q_i \ i = [1, 2, 3 \ldots r] \) is a set of generalized coordinates, the generalized forces or moments acting in direction of coordinates \( Q_i \) can be denoted by forces, and the Lagrangian function \( T \) is defined as the product of the kinetic and potential energies:

\[
T = E_k(q_1, q_2, \ldots, q_r, \dot{q}_1, \ldots, \dot{q}_r) - E_p(q_1, \ldots, q_r) \tag{2}
\]
in which $E_k$ is the kinetic energy and $E_p$ presents the potential energy. For the DIP system presented in Figure 1, the kinetic and potential energies can be determined by summing up the individual components' energies [7]. The independent coordinate parameters of the system are $x_c$, $\alpha$ and $\theta$. Considering the external force $F_c$ applied to the system along the $x$ coordinate and ignoring the friction of the system, equation (1) can be expanded as follows:

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_c} \right) - \frac{\partial T}{\partial x_c} = u \quad (3)$$

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\alpha}} \right) - \frac{\partial T}{\partial \alpha} = 0 \quad (4)$$

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\theta}} \right) - \frac{\partial T}{\partial \theta} = 0 \quad (5)$$

The equation of motion for a double inverted pendulum (DIP) system can be written as:

$$T = \sum_{i=1}^{n} E_{k(i\ldots3)} - \sum_{j=1}^{m} E_{p(i\ldots3)} \quad (6)$$

$$E_{k\text{total}} = E_k^{\text{cart}} + E_k^{\text{pend}_1} + E_k^{\text{pend}_2} \quad (7)$$

$$E_{p\text{total}} = E_p^{\text{cart}} + E_p^{\text{pend}_1} + E_p^{\text{pend}_2} \quad (7)$$

$E_k^{\text{pend}_1} = \frac{1}{2} m_1 \dot{x}_c^2 + \frac{1}{2} (m_l l_1^2 + l_1^2) \dot{\alpha}^2 + m_1 l_1 \dot{x}_c \dot{\alpha} \cos(\alpha) \quad (8)$

$E_k^{\text{pend}_2} = \frac{1}{2} m_2 \dot{\theta}_2^2 + \frac{1}{2} m_2 l_2^2 \dot{\alpha}_2^2 + \frac{1}{2} (m_2 l_2^2 + l_2) \dot{\alpha}_2^2 + m_2 \dot{x}_c (l_1 \dot{\alpha} \cos(\alpha) + l_2 \dot{\theta}_2 \cos(\theta)) + m_2 l_1 l_2 \dot{\alpha} \cdot \dot{\theta} \cos(\alpha - \theta) \quad (8)$

$E_p^{\text{cart}} = 0 \quad (9)$

$E_p^{\text{pend}_1} = m_2 g (l_1 \cos(\alpha) + l_2 \cos(\theta)) \quad (9)$

$E_p^{\text{pend}_2} = m_2 g (l_1 \cos(\alpha) + l_2 \cos(\theta)) \quad (9)$

Substituting energy equations in equation 1, the Lagrangian function of the system becomes:

$$T = \frac{1}{2} (m_c + m_{p1} + m_{p2}) \dot{x}_c^2 + \frac{1}{2} (m_{p1} l_1^2 + m_{p2} l_1^2 + l_1) \dot{\theta}_1^2 + \frac{1}{2} (m_2 l_2^2 + l_2) \dot{\theta}_2^2 + (m_1 l_{p1} + m_2 l_1) \cos \alpha \dot{x}_c \dot{\alpha} + m_2 l_{p2} \cos \alpha \dot{x}_c \dot{\theta} + m_2 l_1 l_{p2} \cos(\alpha - \theta) \dot{\alpha} \dot{\theta} - (m_1 l_{p1} + m_2 l_1) g \cos \alpha - m_2 l_{p2} g \cos \theta \quad (10)$$

Using the obtained result for $T$, equations 3, 4 and 5 can be rewritten as follows:

$$u = m_c \dot{x}_c + (m_{p1} l_{p1} + m_{p2} l_1) \cos \alpha \dot{\alpha} + m_{p2} l_{p2} \cos \theta \dot{\theta} - (m_{p1} l_{p1} + m_{p2} l_1) \sin \alpha \dot{\alpha}^2 - m_{p2} l_{p2} \sin \theta \dot{\theta}^2$$

$$0 = (m_{p1} l_{p1} + m_{p2} l_1) \cos \alpha \dot{x}_c + (m_{p1} l_1^2 + m_{p2} l_1^2 + l_1) \dot{\alpha} + \ddot{\alpha}$$

$$m_{p2} l_{p2} \cos(\alpha - \theta) + m_{p2} l_1 l_{p2} \sin(\alpha - \theta) \dot{\theta}^2 - (m_{p1} l_{p1} + m_{p2} l_1) g \sin \alpha$$

$$0 = m_{p2} l_{p2} \cos \theta \dot{x}_c + m_{p2} l_1 l_{p2} \cos(\alpha - \theta) \dot{\alpha} + (m_{p2} l_2^2 + l_2) \dot{\theta} - m_{p2} l_{p2} g \sin \theta - m_{p2} l_1 l_{p2} \sin(\alpha - \theta) \dot{\alpha}^2$$

The equation 10 presents the compact matrix form of the last three equations:

\[ \mathbf{H}(\gamma)\ddot{\gamma} + \mathbf{M}(\gamma, \dot{\gamma})\dot{\gamma} + \mathbf{F}(\gamma) = \mathbf{L}u \]  

where:

\[ \gamma = (x_c \ x \ \theta)^T \]

\[ \mathbf{H}(\gamma) = \begin{pmatrix} a_1 & a_2\cos\alpha & a_3\cos\theta \\ a_2\cos\alpha & a_4 & a_5\cos(\alpha - \theta) \\ a_3\cos\theta & a_5\cos(\alpha - \theta) & a_6 \end{pmatrix} \]

\[ \mathbf{M}(\gamma, \dot{\gamma}) = \begin{pmatrix} 0 & -a_2\sin\alpha \dot{\alpha} & -a_3\sin\theta \dot{\theta} \\ 0 & 0 & a_5\sin(\alpha - \theta) \dot{\theta} \end{pmatrix} \]

\[ \mathbf{F}(\gamma) = \begin{pmatrix} -\xi_1\sin\alpha \\ -\xi_2\sin\theta \end{pmatrix} \]

\[ \mathbf{L} = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix}^T \]

From Figure 1, it can be seen that the centre of mass of the rods is at the geometrical centre for both rods “l_{p1}” and “l_{p2}” will be “l_1/2” and “l_2/2”. As a result, parameters \( a_i (i = 1, 2, ..., 6) \) will be defined as:

\[ \begin{align*} 
    a_1 &= m_c + m_{p1} + m_{p2} \\
    a_2 &= \left( \frac{1}{2} m_{p1} + m_{p2} \right) l_1 \\
    a_3 &= \frac{1}{2} m_2 l_2 \\
    a_4 &= \left( \frac{1}{3} m_{p1} + m_{p2} \right) l_1^2 \\
    a_5 &= \frac{1}{2} m_{p2} l_1 l_2 \\
    a_6 &= \frac{1}{3} m_{p2} l_2^2 \\
    \xi_1 &= \left( \frac{1}{2} m_{p1} + m_{p2} \right) l_1 g \\
    \xi_2 &= \frac{1}{2} m_{p2} l_2 g 
\end{align*} \]  

The nonlinear form of the state equation can be obtained by considering equation 12, multiplying it by the matrix \( \mathbf{H}^{-1}(X) \), defining the state variables, and substituting those variables into the equation.

\[ \begin{pmatrix} \dot{X}_1 \\ \dot{X}_5 \\ \dot{X}_6 \end{pmatrix} = -\frac{\mathbf{M}(\gamma, \dot{\gamma})}{\mathbf{H}(\gamma)} \begin{pmatrix} X_4 \\ X_5 \\ X_6 \end{pmatrix} + \frac{1}{\mathbf{H}(\gamma)} \left[ \mathbf{L}u - \mathbf{F}(\gamma) \right] \]  

\[ \begin{align*} 
    X_1 &= x_c; \\
    X_2 &= \alpha; \\
    X_3 &= \theta; \\
    X_4 &= \dot{x}_c; \\
    X_5 &= \dot{x}_c; \\
    X_6 &= \dot{\theta}; \\
    \dot{X}_1 &= X_4; \\
    \dot{X}_2 &= X_5; \\
    \dot{X}_3 &= X_6; \\
    \dot{X}_4 &= \ddot{x}_c; \\
    \dot{X}_5 &= \ddot{x}_c; \\
    \dot{X}_6 &= \ddot{\theta} \end{align*} \]  

The equation (16) could be written in a following compact form as well:

\[ \dot{X} = \begin{bmatrix} 0 & -I & 0 \\ 0 & \frac{\mathbf{M}(\gamma, \dot{\gamma})}{\mathbf{H}(\gamma)} & 0 \end{bmatrix} X + \begin{bmatrix} 0 & \frac{\mathbf{F}(\gamma)}{\mathbf{H}(\gamma)} \end{bmatrix} u + \begin{bmatrix} 0 & \frac{\mathbf{L}u - \mathbf{F}(\gamma)}{\mathbf{H}(\gamma)} \end{bmatrix} \]  

The Lagrangian function has been used to derive the dynamic model of the DIP system and the nonlinear form of the state equation. In the following section, the parameters in equation 16 will be identified through system identification of the DIP system. In order to identify the unknown parameters \( a_{i1}, a_{i2}, a_{i3}, a_{i4}, a_{i5}, a_{i6}, \xi_3, \xi_2 \), presented in equation 16, the online system identification will be conducted by applying the energy theorem. In order to solve for \( a_i \), equations must be formed. This requires collecting online data from the real system. In the following, the details of the DIP setup used in this project will be explained.
3 Swing-Up and Stabilisation of DIP

We used two control strategies to move the pendulum from its descending position to the vertical upright position and keep it there: one to swing up the pendulum and the other to balance the pendulum parts with a minimal amount of error for a rapid attainment of the dead position [8]. The state-space equation for the stance control system used was \( \dot{z} = \mathcal{H} \cdot z + \mathcal{M} \cdot u + \mathcal{F} \), where the variables \( \mathcal{H} \) and \( \mathcal{M} \) are the system matrix and \( \mathcal{H} \) is a concentrated disturbance that contains a disturbance due to an oscillating connection of the pendulum [9]. Thus, \( z_e \in (e_z, \dot{e}_z) \) represented the error state vector, the desired state vector was \( z_d \), and the actual state vector was \( z_a = (z - z_d) \). The equation \( \dot{z} = \Pi \cdot |z|^X \cdot \text{sign}(z) \) used differentiating sliding models \( \dot{z} = \mathcal{K}^T \dot{z}_e \), and then, we substitute the actual state vector \( \dot{z}_a = (\dot{z} - \dot{z}_d) \); therefore, we obtained the sliding model \( \dot{z} = \mathcal{K}^T (\dot{z} - \dot{z}_d) \). If \( z_d \in \left( \pm \frac{n}{2} \right) \) was the desired vector, the derivative vector was \( \dot{z}_d \in (0,0) \). The conditions given above were to integrate the control \( u = -\frac{1}{\mathcal{K}^T \mathcal{B}} \cdot [\mathcal{K}^T \mathcal{H} \cdot z + \Pi \cdot |z|^\beta \cdot \text{sign}(z)] \); it was swing-up control, and the exchanging gain \( \Pi \) was more noteworthy than the greatest furthest reaches of the \( \mathcal{K}^T \mathcal{H} \) guarantee sliding [9]. The linear inverted pendulum system was a fourth-order system, and the state space was obtained with Equations (13) and (16), where \( z \in \mathbb{R}^{4 \times 1} \), \( \mathcal{H} \in \mathbb{R}^{4 \times 4} \), and \( \mathcal{M} \in \mathbb{R}^{4 \times 1} \). On the basis of the above equation, the incorporated control is \( u = -\frac{1}{\mathcal{K}^T \mathcal{B}} \cdot [\mathcal{K}^T \mathcal{H} \cdot z + \Pi \cdot |z|^\beta \cdot \text{sign}(z) - \mathcal{K}^T \dot{z}_d] \) and the swing up control is presented [9].

3 Simulation results in Matlab/Simscape

Simscape Multibody enables you to connect 3D mechanical models created in SolidWorks and simulate their dynamic behaviour. The process involves exporting a SolidWorks model as an XML file and then importing the XML file into Simscape Multibody. Once you have imported the XML file into Simscape Multibody, you can configure the model and create a simulation. You can then run the simulation to obtain results such as the motion of the parts [13], the forces between the parts, and the energy dissipated by the system. You can also add sensors and actuators, such as force and torque sensors, to measure the dynamic behaviour of the system. Simulation in Simscape Multibody from SolidWorks is an efficient and convenient way to analyse the dynamic behaviour of 3D mechanical structures. It enables you to assess the performance of your design, identify any potential problems, and make the necessary adjustments [10] quickly and accurately.
In the figure 3 and figure 3.a are presented the block diagram of the simscape model.

3  **Experimental results on the QUARC Real-Time**

This section explains the hardware and system components used to successfully build and balance the pendulum. Figure 4 shows the system setup used for this project.
This section shows the experimental results of the combined sensitivity of our controller in comparison with PID-LQR and simulation. The platform of the DIP system is shown in Figure 12.

The experimental results are shown in Figures 5, 6, 7, 8, 9, 10, 11 and 12. Figure 5 shows LQR responses of the cart position $x_c$. Figure 6 and Figure 7 shows the responses of the pendulum angle $\alpha$ and $\theta$. Figure 8 and Figure 9 shows the responses of the pendulum angle velocity $\dot{\alpha}$ and $\dot{\theta}$. Figure 10 and Figure 11 shows the responses of the pendulum comparison angle $\alpha$ and $\theta$ between LQR and PID measured values. Figure 12 shows the responses comparison between simulated and measured values of amplifier voltage $V_m$.

**Fig. 5** Responses of the cart position $x_c$

**Fig. 6** LQR comparison between simulated and measured values of the pendulum angle $\alpha$
Fig. 7 LQR comparison between simulated and measured values of the pendulum angle $\theta$

Fig. 8 LQR comparison between simulated and measured values of the pendulum angle $\dot{\theta}$

Fig. 9 LQR comparison between simulated and measured values of the pendulum angle $\ddot{\theta}$

Fig. 10 Comparison between LQR and PID measured values of the pendulum angle $\theta$
CONCLUSION

This project presented an approach for designing a real-time control system for a double inverted pendulum using a combination of PID and LQR. The results of the real-time simulation showed that both the PID and LQR controllers were successful in swinging up and stabilizing the double inverted pendulum. This project also demonstrated the effectiveness of combining classical and modern control techniques to design a real-time control system for a complex, nonlinear dynamic system.
